HISTORICAL CLIMATOLOGY SERIES 6-4

Climates of the World

January 1969

Reprinted 1972

Revised 1991 (minor revisions)

Preface

This publication updates similar data which appeared in "Climate and Man," the 1941 Yearbook of Agriculture. The principal features of climates of all the continents are discussed briefly. Worldwide temperatures and precipitation are illustrated by maps. Monthly and annual temperatures and precipitation, including extreme temperatures, are presented in tabular form for approximately 800 stations throughout the world.

Whenever possible, data are provided for at least one location in each country throughout the world. Cities in larger countries such as Canada, the USSR, and the United States were selected to provide as complete a geographical coverage as possible. This accounts for the occasional omission of large or well-known cities.

A number of sources were consulted in the preparation of the tables. Readily available long-term climatic summaries were used whenever possible. In some cases such summaries were prepared from long series of monthly data available in the NOAA library or the NCDC files.

The work of planning and preparing this publication was done by Henry Hacia and Charles S. Vitale under the direction of Morris A. Arkin. The 1991 revision was undertaken by David A. McKittrick.

Temperature Distribution

The distribution of temperature over the world and its variations through the year depend primarily on the amount of radiant energy received from the sun in different regions. This in turn depends mainly on latitude but is greatly modified by the locations of continents and oceans, prevailing winds, oceanic circulation, topography, and other factors.

Maps showing average temperatures over the surface of the earth for January and for July are given in figures 1 and 2.

In the winter of the Northern Hemisphere (fig. 1) it will be noted that the poleward temperature gradient (the rate of fall in temperature) north of latitude 15° is very steep over the interior of North America. This is shown by the fact that the lines indicating changes in temperature are very close together. The temperature gradient is also steep toward the cold pole over Asia—the area marked -40° . In western Europe, to the east of the Atlantic Ocean and the Gulf Stream (a region of prevailing westerly winds), the temperature gradient is much more gradual. This is indicated by the fact that the isotherms, or lines of equal temperature, are far apart. In the winter of the Southern Hemisphere (fig. 2), the temperature change toward the South Pole is very gradual, and the isothermal departures from the east-west direction are not as evident because continental effects are largely absent.

In the summers of the two hemispheres—July in the north and January in the south—the temperature gradients are very much diminished as compared with those during

the winter. This is especially marked over the middle and higher northern latitudes because of the greater warming of the extensive interiors of North America and Eurasia than of the smaller land areas in middle and higher southern latitudes.

Distribution of Precipitation

Whether precipitation (fig. 3) occurs as rain or snow or in the rarer forms of hail or sleet depends largely on temperature. This may be influenced more by elevation than by latitude, as in the case of the perpetually snowcapped mountain peaks and glaciers near the Equator in both South America and Africa.

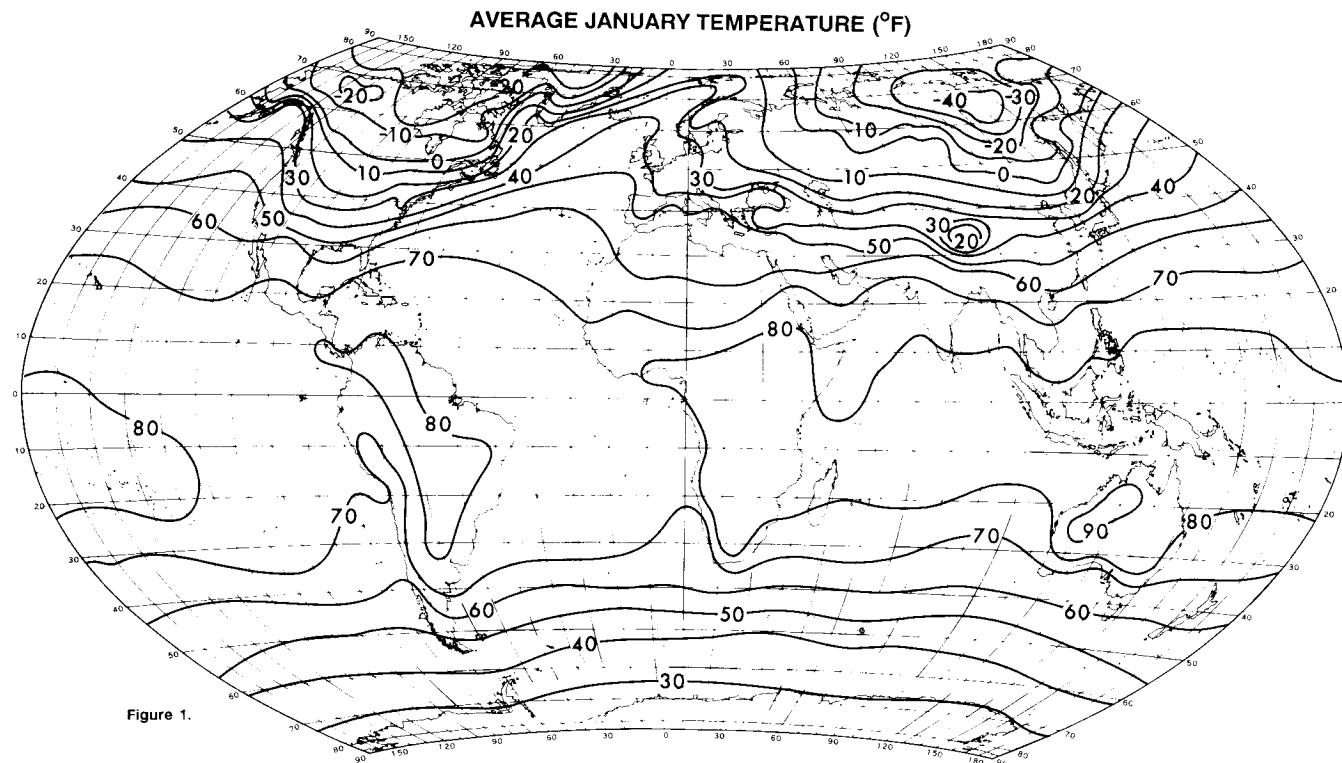

The quantity of precipitation is governed by the amount of water vapor in the air and the nature of the process that leads to its condensation into liquid or solid form through cooling, usually by a moist air mass being forced to rise. Air may ascend to great elevations through local convection (as in thunderstorms or tropical rains); it may be forced up over topographical elevations by the prevailing wind (as on the southern or windward slopes of the Himalayas in the path of the southwestern monsoon of India); or it may ascend gradually in migratory low-pressure formations in which the frontal meeting of warm and cool air masses causes the moist air to rise and condense.

The areas of heaviest precipitation are generally located in tropical regions where the greatest amount of water is present in the atmosphere and the greatest

evaporation takes place, although rainfall can occur only where conditions favor condensation. Certain regions in high latitudes, such as southern Alaska and southern Chile also show great amounts of precipitation where relatively warm moist winds blowing off the ocean undergo a forced ascent over coastal mountain ranges.

In the dry polar regions the water-vapor content of the air is always very low because of the low temperature and very limited evaporation. The other major dry areas

are the subtropical belts of high atmospheric pressure (in the vicinity of latitude 30° on all continents, especially from the extreme western Sahara over a broad, somewhat broken belt to the Gobi Desert) and the arid strips on the lee sides of mountains whose windward slopes have heavy precipitation. These are caused by conditions which, even though the temperature may be high, are unfavorable to the condensation of whatever water vapor may be present in the atmosphere.

North America

North America is nearly all within middle and northern latitudes and therefore much of its interior displays the continental type of climate with notable seasonal temperature extremes.

Along the coasts of southeastern Alaska, western Canada, and the northwestern part of the United States, moderate midsummer temperatures are in marked contrast

to those prevailing in the interior east of the mountains. (Note, for example, the great southward dip of the 60°F isotherm along the west coast in fig. 2). Similarly, the mild midwinter temperatures in the coastal areas stand out against the severe conditions to be found from the Great Lakes region northward and northwestward (fig. 1).

In the Caribbean region, temperature conditions are subtropical while in Mexico and Central America, climatic zones depend on elevation, ranging from subtropical to

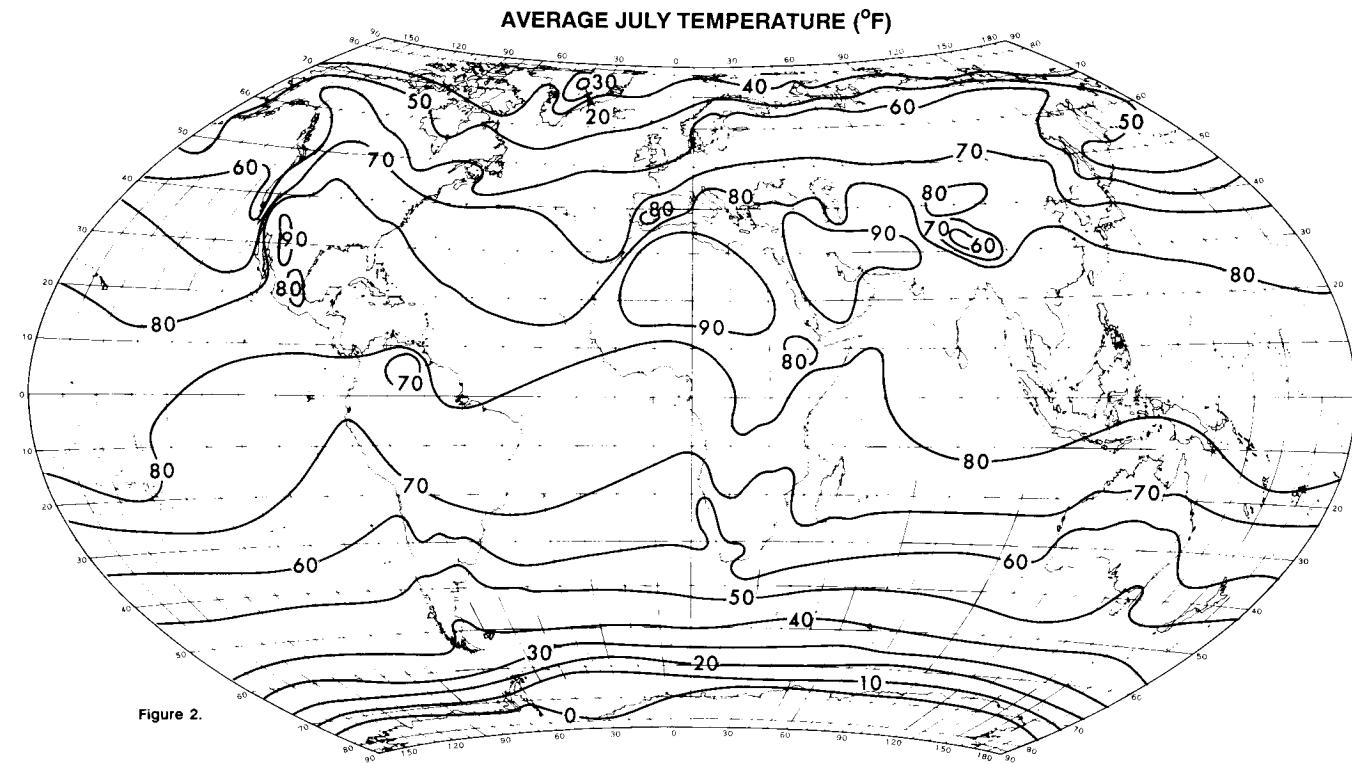

Figure 2.

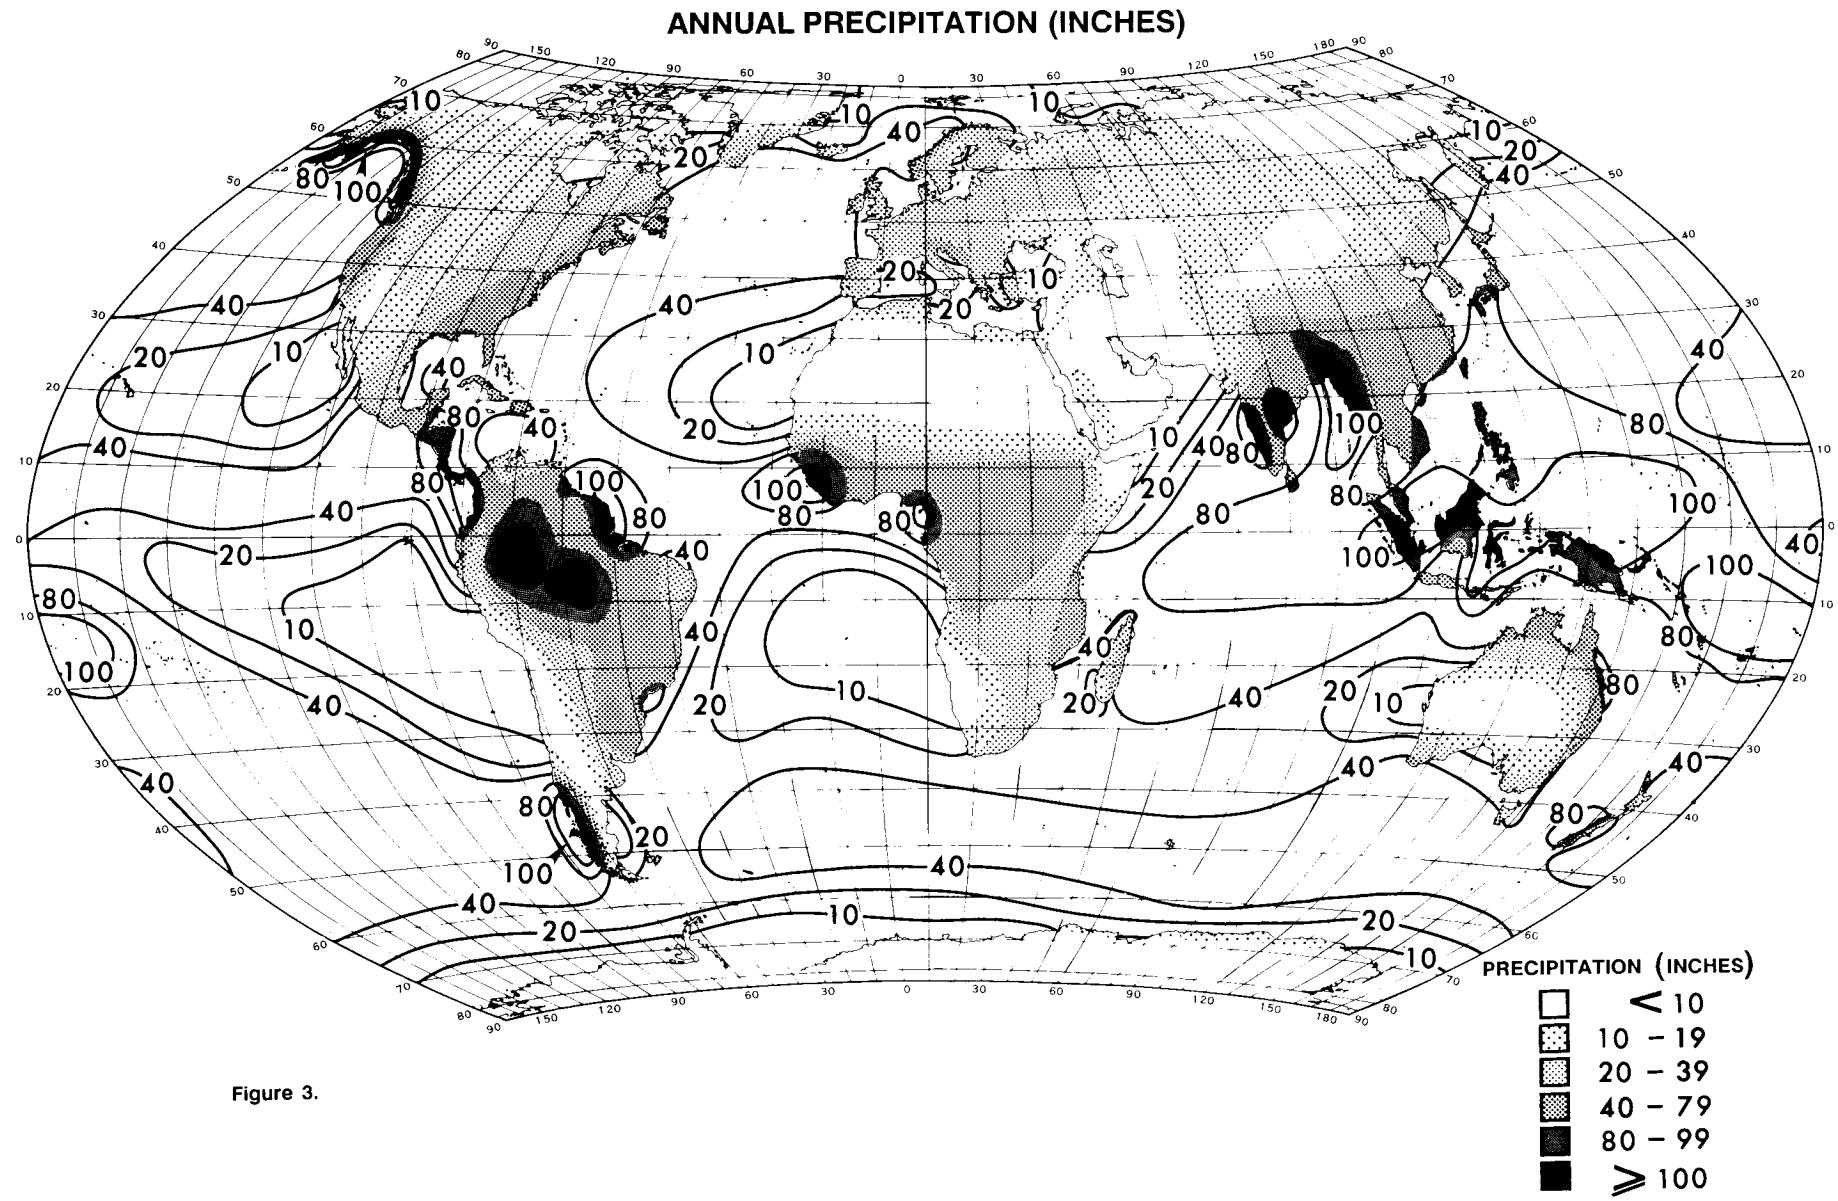

Figure 3.

temperate in the higher levels.

The prevailing westerly wind movement carries the continental type of climate eastward over the United States, so that the region of maritime climate along the Atlantic Ocean is very narrow.

The northern areas are very cold, however, the midwinter low temperatures fall far short of the records set in the cold-pole area of northeastern Siberia, where, because the land area is more vast, it becomes much colder than the smaller land area of northern Canada.

From the Aleutian Peninsula to northern California, west of the crests of the mountains, there is a narrow strip where annual precipitation is over 40 inches, even exceeding 100 inches locally on the coast of British Columbia. East of this belt there is an abrupt decrease in precipitation to less than 20 inches annually from the Gulf of California northward, and to less than 5 inches in parts of the southwestern United States.

In the eastern part of the continent from the southern United States northeastward to Newfoundland, the average annual precipitation is more than 40 inches. Rainfall in the Caribbean, southern Mexico, and Central America is generally abundant. It varies widely, however, even within short distances, especially from the windward to the leeward sides of the mountains.

South America

A large part of South America lies within the tropics and has a characteristically tropical climate. The

remaining narrow southern portion is not subject to the extremes of heat and cold that are found where wide land areas give full sway to the continental type of climate with its hot summers and cold winters. Temperature anomalies unusual for a given latitude are to be found mainly at the high elevations of the Andes stretching from the Isthmus of Panama to Cape Horn.

The Antarctic Current and its cool Humboldt branch skirting the western shores northward to the Equator, together with the prevailing on-shore winds, exert a strong cooling influence over the coastal regions of all the western countries of South America except Colombia. Along the eastern coast, the southerly moving Brazil current from the tropics has a warming effect except along Argentina's southern coast.

In the northern countries of South America, the sharply contrasted dry and wet seasons are the result of the trade winds. In the dry season (corresponding to winter in the Northern Hemisphere), these winds sweep the entire region, while during the wet season (corresponding to summer in the Northern Hemisphere) calms and variable winds prevail. In the basin of the Amazon River, the rainfall is related to the equatorial belt of low pressure and to the trade winds, which give the maximum amounts of rainfall in the extreme west, where the winds ascend the Andean slopes.

The desert areas on the west coast of South America, extending from the Equator southward to the latitude of Santiago, are due primarily to the cold Humboldt or Peruvian Current and upwelling cold coastal water. The moist, cool ocean air is warmed in passing over the land, with a consequent decrease in relative

humidity, so that the dew point is not reached and condensation of vapor does not occur until the incoming air has reached high elevations in the Andes, where temperatures are much lower than along the coast.

In southern Chile, the summer season has moderate rainfall, and winters are excessively wet. The land does not get as much heating and so the prevailing winds remain cooler and condensation of moisture from the ocean progresses from the shores up to the crests of the Andes. By the time the air passes these elevations, however, the moisture has been depleted that the winds on the leeward slopes are dry, becoming more so as they are warmed on reaching lower levels. The mountains cast a great "rain shadow" (an area of little rain) over southern Argentina.

Europe

In Europe there is no extensive north-south mountain system such as is found in the Americas. The general east-west direction of the ranges in the south allows the conditions in the maritime west to change rather gradually toward Asia. Generally rainfall is heaviest on the western coasts, where locally it exceeds 60 inches annually, and diminishes toward the east to less than 20 inches in eastern Russia. Exceptions to this rule occur in the elevated regions of the Alps and the Caucasus. There is a well-defined rain shadow in Scandinavia, with over 60 inches of rain in western Norway and less than 20 inches in eastern Sweden.

Over much of Europe precipitation is both abundant and evenly distributed throughout the year. In those areas where there is a seasonal distribution, namely around the Mediterranean, most of the precipitation comes in the winter, with very dry summers.

Isothermal lines generally parallel the lines of latitude except in winter, when the modifying influence of the Gulf Stream causes a pronounced east-west gradient. There are few marked dips in isotherms due to elevation or continental type of climate such as are found in North America. In Scandinavia, however, the winter map shows an abrupt fall in temperature from the western coast of Norway to the eastern coast of Sweden. The coastal mountains eliminate the modification of the ocean, thus allowing a greater range of temperatures.

Asia

The vast extent of Asia gives full opportunity for continental conditions to develop with a cold area of high barometric pressure in winter and a hot low-pressure area in summer. The former is northeast of the Himalayas and the latter stretches widely from west to east in the latitude of northwestern China. These distributions of pressure give southeastern Asia the well-known monsoon seasons.

In winter, the air circulation is outward over the land from the cold pole, and precipitation is very light over the entire continent. In summer, however, there is an inflow of air from the oceans and the southeastern trade winds cross the equator and merge into the southwestern

monsoon which crosses India. This saturated air produces abundant rain over most of that country, with excessively heavy amounts where the air is forced to rise, even to moderate elevations. At Cherrapunji (4,455 feet), on the southern side of the Khasi Hills in Assam, the average rainfall in a winter month is about 1 inch, while in both June and July it is approximately 100 inches per month. Further north, the summer rainfall meets an impassable barrier in the Himalaya Mountains. A much weaker summer monsoon brings rainfall to Japan and eastern Asia but does not extend far into China because of lower elevations. Consequently, while the southeastern quadrant of Asia has heavy to excessive annual rainfall, the remainder of the continent is dry, with vast areas receiving less than 10 inches annually.

North of the Himalayas the low plains are extremely cold in winter although temperatures rise considerably in summer. At Verkhoyansk which is just north of the Arctic Circle, the mean maximum temperature in January is about -54°F, and in July approximately 66°F. The extreme records are a maximum of 98°F and a minimum of -90°F.

In southwestern Asia (west of India), the winter temperature control is still the interior high-pressure area, and temperatures are generally low as a result of the cool air outflow. Summers are excessively hot and, because the area is beyond the path of the monsoonal flow, precipitation is minimal year round.

Africa

Africa, like South America, lies largely within the tropics and thus temperature distribution is determined mainly by altitude. Moreover, the cool Benguela Current sweeps the southwestern coast as do the warm tropical currents of the Indian Ocean on the southeastern coast, creating conditions closely paralleling those found around the South American continent. In the tropical climatic areas of Africa, conditions are characterized by prevailing low barometric pressure, with convectional rainfall and seasonal northward and southward movement of the heat equator, while in both the north and the south the ruling influences are the belts of high barometric pressure.

Desert conditions typified by the Sahara extend from the Atlantic to the Red Sea and from the Mediterranean southward well beyond the Tropic of Cancer. The Atlas mountains, in the northwest of this region, have the most precipitation as they sit in the path of the moist trade winds.

South of the Sahara, rainfall is much more abundant especially from the west coast to the east African rift valley, with annual maxima of over 100 inches in the region around Sierra Leone. East of the rift valley precipitation is much less, varying from about 40 inches to less than 10 inches on the coast of Somalia. Moving south towards the Tropic of Capricorn, the rainfall totals are also much less especially on the west coast.

The heavy rainfall over sections of Ethiopia from June to October, when more than 40 inches may fall, is one of the earth's outstanding examples of seasonal

distribution of rainfall.

Moist equatorial climate is typified by conditions in Zaire; arid torrid climate, by those of Egypt and the Sahara and moderate plateau climate by those found in parts of Ethiopia, Kenya, and Tanzania.

Australia

In the southern winter high-pressure sits over the interior of Australia, and all except the southernmost parts of the continent are dry. In summer, this pressure belt moves south of the continent with dry conditions persisting over the southern and western areas. Thus much of the continent has less than 20 inches of precipitation each year except in the extreme southwest and in a strip circling

from southeast to northwest. The average annual precipitation in most of the interior, especially to the south, is less than 10 inches.

On the southern coast, the winter precipitation is the cyclonic type, the heavy summer rains of the north are of monsoon origin and those of the east are in large part orographic, owing to the mountains along the coast. On the ocean-facing east slopes of these mountains, the mean annual rainfall is over 40 inches and in many localities over 60 inches. This is also true for areas affected by the monsoon rains in the north.

Because of the location of Australia, on both sides of the Tropic of Capricorn, temperatures far below freezing are to be found only in the south at high elevations. In the arid interior, extreme maximum temperatures rank with those of the hottest regions of the earth.

- NOTES:
- "Record Length" refers to average daily maximum and minimum temperatures and precipitation. A standard period of the 30 years from 1931-1960 had been used for locations in the United States and some other countries. The length of record of extreme maximum and minimum temperatures includes all available years of data for a given location and is usually for a longer period.
 - * - Less than 0.05" but more than 0".
 - Except for Antarctica, amounts of solid precipitation such as snow or hail have been converted to their water equivalent. Because of the frequent occurrence of blowing snow, it has not been possible to determine the precise amount of precipitation actually falling in Antarctica. The values shown are the average amounts of solid snow accumulating in a given period as determined by snow markers. The liquid content of the accumulation is undetermined.
